

## **TruDoss General Information**

As we add information to immutably preserve to either our document and image partner, TransPerfect, or a customer's existing file repository, the information is processed in bundles called blocks, which are validated within seconds of submission. These blocks are chained together in an immutable, sequential, and irreversible fashion to collectively form a private ledger upon which our patent (#11,061,886) was created. Multiple nodes work cohesively to verify and process those transactions and update the ledger. The integrity of valuable data and blocks immutably associate the original file, regardless of file type or data set, with a cryptographic hash. Anyone who makes changes to the information will create a new hash which is not associated with the original file. Our validation process will return a negative response instantly when an altered document is compared to one which has been hashed and made immutable by TruDoss.
